

TorneLIB version story

This story takes place from the year 2000 and forward.

From the absolute beginning we had TorneEngine, but during that time the working title was just "Tornevall" and created for internal use only. By time, developing a very hardcoded framework would'nt work nice for long, so this is where TorneEngine v2 actually took place. Inspired by [vBulletin](#) a small project of classes too form in a bit more serious manner than version 1. By time, the developer got employed on a company, that actually needed to build various application and preferrably the needs of building them fast. Some methods was cloned from v1 and version 2 was created. But still, the code was quite messy, since it was only a clone of v1. By this time, TorneEngine became also became the side project **PHPCore** (also partially known, as inofficial working name TeleEngine) to make it lesser personalized and "name independent".

In the same moment, uncomfortable with still to many dependencies in PHPCore and TorneEngine we tried to build version 3, where all function was rewritten from scratch as far as it was possible. Time flied by and we started working with ecommerce applications at a professional level. Documentation got important and this site was created. From august 2015 to december 2015 a lot of work happened and in the end of December, a shitload of plans was made to make a large library targeted for public API's and to merge smaller frameworks to simplify function calls to them. So here we are, with work in progress where TornevallWEB version 5 is one of our primary targets to rebuild with a much higher level of structure than before.
